

Semantics: Redex

A **redex** is a term of the form

$(\lambda x \rightarrow e1) e2$

REDEX

A function $(\lambda x \rightarrow e1)$

- x is the *parameter*
- $e1$ is the *returned* expression

Applied to an argument $e2$

- $e2$ is the *argument*

Semantics: β -Reduction

A **redex** b -steps to another term ...

$$(\lambda x \rightarrow e1) e2 \quad =_b \quad e1[x := e2]$$

where $e1[x := e2]$ means

“ $e1$ with all *free* occurrences of x replaced with $e2$ ”

Computation by *search-and-replace*:

- If you see an *abstraction* applied to an *argument*, take the *body* of the abstraction and replace all free occurrences of the *formal* by that *argument*
- We say that $(\lambda x \rightarrow e1) e2$ β -steps to $e1[x := e2]$

Redex Examples

$(\backslash x \rightarrow x)$ apple \Rightarrow apple
=b> apple

Is this right? Ask Elsa (<http://goto.ucsd.edu:8095/index.html#?demo=blank.lc>)!

QUIZ

$(\lambda x \rightarrow (\lambda y \rightarrow y)) \text{ apple}$
 $=b> ???$

BODY ARG

$\text{BODY}[x := \text{ARG}]$
 \downarrow
 BODY

- A. apple
- B. $\lambda y \rightarrow \text{apple}$
- C. $\lambda x \rightarrow \text{apple}$
- D. $\lambda y \rightarrow y$
- E. $\lambda x \rightarrow y$

NEW

QUIZ

$(\lambda x \rightarrow y\ x\ y\ x)$ apple
 =b> ???

formal (points to λx)
body (points to $y\ x\ y\ x$)
arg (points to apple)

- A. apple apple apple apple

B. y apple y apple ✓

- C. y y y y
- D. apple

QUIZ

`(\x -> x (\x -> x)) apple`
=b> ???

cse230
free

A. `apple (\x -> x)`

B. `apple (\apple -> apple)`

C. `apple (\x -> apple)`

D. `apple`

E. `\x -> x`

EXERCISE

What is a λ -term `fill_this_in` such that

`fill_this_in apple`

`=b> banana`

ELSA: <https://goto.ucsd.edu/elsa/index.html>

Click here to try this exercise (https://goto.ucsd.edu/elsa/index.html#?demo=permalink%2F1585434473_24432.lc)

A Tricky One

$(\lambda x \rightarrow (\lambda y \rightarrow x)) y$
 $=b> \lambda y \rightarrow y$

Handwritten annotations:

- DIFF**: A red arrow points from the word "DIFF" to the inner lambda expression $(\lambda y \rightarrow x)$.
- FREE**: A red arrow points from the word "FREE" to the variable y in the argument position.
- BOUND**: A red arrow points from the word "BOUND" to the variable y in the lambda abstraction λy .
- $\lambda y \rightarrow y$: A red arrow points from the lambda abstraction λy to the expression y .

Is this right?

Something is Fishy

$(\lambda x \rightarrow (\lambda y \rightarrow x)) y$
= $\lambda y \rightarrow y$

Is this right?

Problem: The *free* y in the argument has been captured by λy in body!

Solution: Ensure that *formals* in the body are different from *free-variables* of argument!

Capture-Avoiding Substitution

We have to fix our definition of β -reduction:

$$(\lambda x \rightarrow e1) e2 \quad =_{\beta} \quad e1[x := e2]$$

where $e1[x := e2]$ means “ ~~$e1$ with all free occurrences of x replaced with $e2$~~ ”

- $e1$ with all *free* occurrences of x replaced with $e2$
- **as long as no free variables of $e2$ get captured**

Formally:

$$x[x := e] = e$$

$$y[x := e] = y \quad \text{-- as } x \neq y$$

$$(e1 \ e2)[x := e] = (e1[x := e]) (e2[x := e])$$

$$(\lambda x \rightarrow e1)[x := e] = \lambda x \rightarrow e1 \quad \text{-- Q: Why leave `e1` unchanged?}$$

$$(\lambda y \rightarrow e1)[x := e] \\ | \text{ not } (y \text{ in } FV(e)) = \lambda y \rightarrow e1[x := e]$$

DEF

Oops, but what to do if y is in the *free-variables* of e ?

- i.e. if $\lambda y \rightarrow \dots$ may *capture* those free variables?

Rewrite Rules of Lambda Calculus

1. β -step (aka function call)
2. α -step (aka renaming formals)

$$(\lambda x \rightarrow (\lambda y \rightarrow x)) \quad y$$

$\downarrow \alpha\text{-STEP}$

$$(\lambda x \rightarrow (\lambda n \rightarrow x)) \quad y$$

func (x) { return x+1 }

" α -renam"

$\text{func } (y) \{ \text{return } y+1 \}$

Semantics: α -Renaming

$\lambda x \rightarrow e \quad \text{=a>} \quad \lambda y \rightarrow e[x := y]$
 where $\text{not } (y \text{ in } \text{FV}(e))$

$(\lambda x \rightarrow y)$ "glob"
 y

$\lambda y \rightarrow y$ "captured"
 y

- We rename a formal parameter x to y
- By replace all occurrences of x in the body with y

- We say that $\lambda x \rightarrow e$ α -steps to $\lambda y \rightarrow e[x := y]$

Example:

$\text{fun}(y) \{ \text{ret } y \}$

$\lambda x \rightarrow x =_a \lambda y \rightarrow y =_a \lambda z \rightarrow z$

All these expressions are α -equivalent

$\text{fun}(x) \{ \text{ret } x \}$

$\text{fun}(z) \{ \text{ret } z \}$

What's wrong with these?

-- (A)

$\lambda f \rightarrow f x =_a \lambda x \rightarrow x x$

Do not replace
the FREE 'y'

-- (B)

$(\lambda x \rightarrow \lambda y \rightarrow y) y =_a (\lambda x \rightarrow \lambda z \rightarrow z) z$

FREE

Tricky Example Revisited

$(\lambda x \rightarrow (\lambda y \rightarrow x)) y$

=a> $(\lambda x \rightarrow (\lambda z \rightarrow x)) y$

=b> $\lambda z \rightarrow y$

-- rename 'y' to 'z' to avoid capture

-- now do b-step without capture!

To avoid getting confused,

- you can **always rename formals,**
- **so different variables have different names!**

Normal Forms' = Has No Redex

Recall **redex** is a λ -term of the form

$(\lambda x . e_1) e_2$

A λ -term is in **normal form** if it contains no redexes.

QUIZ

Which of the following term are not in normal form ?

A. x NF

B. $x y$ NF

ie do NOT CONTAIN ANY
REDEX

✓ C. $(\lambda x \rightarrow x) y$ not NF

$-x$ $-e_1$ $-e_2$

$(\lambda x \rightarrow e_1) e_2$

D. $x (\lambda y \rightarrow y)$ NF

~~E. C and D~~

Semantics: Evaluation

A λ -term e evaluates to e' if

1. There is a sequence of steps

$$\begin{array}{l}
 e \\
 \stackrel{?}{\Rightarrow} e_1 \\
 \stackrel{?}{\Rightarrow} e_2 \\
 \vdots
 \end{array}$$

$e \Rightarrow e_1 \Rightarrow \dots \Rightarrow e_N \Rightarrow e'$

$\Rightarrow e'$
 \uparrow
NF

where each \Rightarrow is either $=a>$ or $=b>$ and $N \geq 0$

2. e' is in *normal form*

Examples of Evaluation

$(\lambda x . x) \text{ apple}$
 $=b> \text{ apple}$

$(\lambda f \rightarrow f (\lambda x \rightarrow x)) (\lambda x \rightarrow x)$
=?> ???

$(\lambda x \rightarrow x x) (\lambda x \rightarrow x)$
=?> ???

Elsa shortcuts

Named λ -terms:

let ID = $\lambda x \rightarrow x$ -- *abbreviation for* $\lambda x \rightarrow x$

To substitute name with its definition, use a `=d>` step:

ID apple

`=d> (\x -> x) apple` *-- expand definition*

`=b> apple` *-- beta-reduce*

Evaluation:

- `e1 =*> e2`: `e1` reduces to `e2` in 0 or more steps
 - where each step is `=a>`, `=b>`, or `=d>`
- `e1 =~> e2`: `e1` evaluates to `e2` and `e2` is **in normal form**

EXERCISE

Fill in the definitions of **FIRST**, **SECOND** and **THIRD** such that you get the following behavior in `elsa`

```
let FIRST = fill_this_in
let SECOND = fill_this_in
let THIRD = fill_this_in
```

```
eval ex1 :
(((FIRST apple) banana) orange)
  =*> apple
```

```
eval ex2 :
(((SECOND apple) banana) orange)
  =*> banana
```

```
eval ex3 :
(((THIRD apple) banana) orange)
  =*> orange
```

Non-Terminating Evaluation

$$(\lambda x \rightarrow x x) (\lambda x \rightarrow x x)$$
$$=b> (\lambda x \rightarrow x x) (\lambda x \rightarrow x x)$$

Some programs loop back to themselves...

... and *never* reduce to a normal form!

This combinator is called Ω

What if we pass Ω as an argument to another function?

let OMEGA = ($\lambda x \rightarrow x x$) ($\lambda x \rightarrow x x$)

($\lambda x \rightarrow (\lambda y \rightarrow y)$) OMEGA

Does this reduce to a normal form? Try it at home!

Programming in λ -calculus

Real languages have lots of features

- Booleans ✓
- Records (structs, tuples) ✓
- Numbers ✓ *LIST*
- **Functions** [we got those]
- Recursion ✓

$$e ::= x \mid \lambda x \rightarrow e \mid (e_1 e_2)$$

Lets see how to encode all of these features with the λ -calculus.
